Module 7 Final

The waterfall model has been used for development at ChadaTech for many years. The transition to Scrum-Agile methodologies and using these innovative tools provided by Scrum-Agile we can improve product quality and therefore produce a better application for the SNHU Travel project. In this project we seek to expand our client base and provide an ease-of-use application for travelling. This paper reflects on the Sprint Review of this project and the retrospective of our team's transition to Scrum, evaluating the methodology's impact on the project.

In Scrum, every team member has specific roles that contribute to the project and to the team itself. I as a Scrum Master led the events necessary for the team to collaborate together and have clear communication all-while explaining any roadblocks faced by the other team members. The product owner, in this project, is responsible for maintaining the backlog and having clear communication with the stakeholders and ensuring that our goals are aligned with the stakeholders' goals and that the backlogs can be managed properly. The developers ensure that our project is built correctly and that the correct features and tasks are implemented into the application, while the tester checks said application for quality and reports back to the team for any issues found or possible optimizations.

During sprint planning, I the developer during module five; worked closely with the product owner to break down user stories into manageable tasks. This collaboration ensured that everyone understood the scope of the work. When developing it I also asked for clarification from the tester on the issues found with the application. Having a clear line of communication allows feedback during the sprint review and therefore highlights potential issues we as a team

may face and therefore can think on the fly about the work that needs to be done and set our priorities.

The major strength of Scrum-Agiles approach is the user stories and its communication that is understood by the team. User stories are also the essence of the development process, as they allow the team to manage the backlog while tracking the user stories and since the user story represents a specific feature or add-on from the user's perspective. Using sprint planning, the team and I broke down the user stories into smaller tasks and asked for more clarification on specific tasks to make them more manageable for the team.

One such example of the user stories allowing the team to focus on the project and progress towards our goals was the changes in terms of the travel destinations and organization of the destinations. The team was provided with a user story about changes that needed to be made, the organization of the travel destinations needed to be determined as well as the locations and descriptions of them as well. The user story was clear and concise and therefore also allowed the team to strategize, design, and build the feature quickly and efficiently based around the user story provided. Thus, the user story was completed successfully, and later reimplemented when the stakeholders wanted a change in themes for the destinations.

Interruptions are also considered an issue for projects and teams, especially when changes occur to a project midway through development. This particular project requested additional features and instead of delaying the project the team and I adapted as mentioned earlier. When it came to changing the destinations, which were destinations, the team deemed worthy of popular travel destinations. The stakeholders wanted health and wellness destinations. The team then immediately worked on that as the priority of the destinations matters more, and the product owner also conveyed that this is a large-scale priority and needed to be done.

Communication and organizational tools are also the cornerstone of the team's success. Daily stand-ups provide the platform needed for every team member to share updates, identify issues, and ask as well as offer help when needed. Organizational tools also allow the team to identify issues and prioritize specific features or addons. A combination of the two of these tools are essentials for Scrum-Agile methodologies. I personally have used Trello before and enjoyed moving goals around when it came to completion and was able to understand where the team was with specific features. A combination of daily stand ups and a breakdown of what needs to be done via whiteboard, or infographics is a great example for how Scrum-Agile methodologies allow work to get done. Information is explained in a 10-to-15-minute stand-up meeting and goals are viewed and understood as well.

The Scrum-Agile approach provides several benefits to product development. This process is great but does also pose some issues. The collaboration, flexibility, and transparency are perfect. The team can work closely together with stakeholders and be better aligned with their goals and priorities all while being able to quickly adapt to changes and add new features when needed without delays. The daily stand-ups and sprint reviews also ensure that progress is followed up by the team and progress is visible. The issue with this methodology is that there is a learning curve and the transition from waterfall to Agile will contain challenges and that there are new roles and challenges to be faced. However, a great Agile team will adapt to these challenges. The other issue is following up on the time commitment as Scrum requires meetings and communication. However, if there were less meetings and less communication then more issues would persist. Therefore, these can both be solved by a dedicated team. Thus, Agile is the way for ChadaTech to go with as the flexibility and adaptability the team can follow are perfect and fit the needs of the company.
